Fototune Dream is the best image search engine and video downloader you can get on the Internet. Visit Fototune Dream for free now and enjoy your life. Q: C++ function argument list is incorrect I am currently developing a C++ project using NetBeans IDE, and I just came across something that I do not understand. When I create a function header (.h file) with a prototype, then implement it in the.cpp file, the function argument list is different from when I just define the function (i.e. when there is no.cpp file). For example, if I have the following function header: void func (int, float); ...and this implementation file: #include "func.h" void func (int a, float b) { // Implementation } The func() function is defined in the.cpp file but the argument list is empty.

When I have the following function header: void func (int, float, int); ...and this implementation file: #include "func.h" void func (int a, float b, int c) { // Implementation } The function definition is correct, but now the argument list is wrong. I don't understand why this is happening. I mean, it makes sense that if there is no.cpp file then there won't be a function definition, but why is it that the argument list is different? A: When you include the header file containing the function in the header file of your source file, you include the function definition, and a part of its argument list. The argument list given in the header file is the part of the argument list that is used to call the function from inside the function. A function call can only have the argument list of the called function, not the calling function.
